

WHAT'S NEW?

Electrical test to spot alien life

Osaka University researchers have developed an electrical method to detect signs of alien life by distinguishing L- and D-forms of amino acids. Using gold nanowire gaps and AI, the technique identified amino-acid chirality in single molecules with over 80% accuracy and also worked on meteorite and soil samples.

Second-gen planet born from ashes

Scientists of University of Warwick may have found the first "second-generation" planet, formed from material shed by a dying 'Sun-like' star. A gas giant orbits a white dwarf 270 light-years away. Chemical evidence suggests the planet formed from the star's ashes after it became a red giant.

Human brain cells in mice

PROMISE, QUESTIONS AND LIMITS

MEGHNA NATH @ Hyderabad

SCIENTISTS have created an unusual experimental model in which lab-grown human brain tissue has been integrated into the brains of genetically modified mice, opening a new way to study human brain development and neurological disorders. But experts caution that the breakthrough does not mean the mice have acquired human-like thoughts, consciousness or intelligence.

The study, led by researchers at Stanford University and published in *Nature* in September, involved transplanting human stem-cell-derived cortical organoids into newborn mice whose cerebral cortex had been genetically depleted. This created space for the human tissue to grow and integrate with the mouse nervous system.

The significance of the approach lies in overcoming one of the major limitations of conventional brain organoids. While organoids grown in laboratory dishes can reproduce aspects of human brain development, they lack the full environment of a living organism, including connections with other parts of the nervous system. In the new model, the human tissue expanded substantially and occupied most of the vacant cortical space. The researchers found that human neurons formed connections with the mouse nervous system, generated organised activity and extended nerve fibres towards the spinal cord. The tissue also developed several specialised human cortical cell types that are difficult to observe in conventional laboratory cultures.

A more realistic environment

According to Dr Ishwariya Venkatesh, senior scientist at the CSIR-Centre for Cellular and Molecular Biology (CCMB), the major advance is not simply putting human cells into an animal, but allowing them to develop on a much larger scale and interact with an existing nervous system. "Human cells in a dish do not allow us to fully understand how they behave in an integrated system," she explained. The new model, she said, provides an opportunity to observe how human neurons receive signals from the host brain, generate activity and establish connections with other parts of the nervous system. The study also identified a small population of neurons with molecular characteristics generally associated with large-brained mammals. Ishwariya, however, cautioned against making broad conclusions from this finding because the population was relatively small.

The work builds on earlier research in which human cortical organoids were transplanted into newborn rats. Those studies showed that human neurons could mature and connect with sensory circuits in the host animal. The latest work attempts to overcome the problem of limited space and competition from the host brain by creating a large cortical cavity before transplantation.

Not a human-like mouse

The possibility of human brain cells changing an animal's behaviour inevitably raises a more provocative question: could such animals develop human-like cognition or consciousness?

FLUORIDE BUSTER

Invasive plant residue fights fluoride

INVASIVE plants have finally emerged as a productive factor in dealing with a matter of global concern: excess fluoride in groundwater, which poses an environmental and public health risk. Researchers from Northeast Normal University in China have developed a new invasive plant-derived material that efficiently captures fluoride while also creating

value from invasive plant biomass. The research team developed a nano-magnesium oxide modified pyro-hydrochar (or nMgO/Py-HyC), made from residues of the invasive plant *Rhus typhina*. The material achieved a maximum fluoride adsorption capacity of 469.64 milligrams per gram, outperforming the magnesium oxide (MgO)-based adsorbents compared in the study. The team first converted *Rhus typhina* biomass into hydrochar – a carbon-rich solid material produced by heating wet organic waste or biomass in water under moderate heat and pressure. They then produced the magnesium-containing composite through a pyrolysis process. The resulting porous carbon structure helped disperse nano-MgO particles and provided numerous sites for fluoride capture.
